Understanding STATCOM and Its Role in Power Systems

What is a STATCOM?

A Static Synchronous Compensator (STATCOM) is a power electronic device designed to regulate voltage by providing or absorbing reactive power in an AC power system. It employs Voltage Source Converters (VSC) to generate a controllable AC voltage that can be synchronized with the system voltage. By adjusting its output, the STATCOM can either supply reactive power to boost voltage levels or absorb reactive power to reduce overvoltage conditions.

Main Components of a STATCOM

The typical components include:

- Voltage Source Converter (VSC): Converts DC to AC power with precise control.
- DC Energy Storage: Usually a capacitor that supplies the DC link voltage.
- Phase-Locked Loop (PLL): Synchronizes the converter output with the grid voltage.
- Filters: To reduce harmonics and ensure power quality.

Modeling the STATCOM in MATLAB

Mathematical Representation

The core of MATLAB modeling involves representing the STATCOM in a manner compatible with system simulation. Typically, the STATCOM is modeled as a controllable voltage source in series with the network impedance, with its amplitude and phase controlled to achieve desired reactive power exchange.

The key equations include:

- Reactive power output: $Q_{\text{STATCOM}} = V_{\text{grid}} \times V_{\text{STATCOM}} \times \sin(\phi)$
- Voltage control: Adjusting V_{STATCOM} and ϕ (phase angle) to regulate system voltage.

Implementing the Model in MATLAB

Using MATLAB/Simulink or script-based modeling, you can define:

- Grid voltage source
- STATCOM voltage source with controllable amplitude and phase
- Control blocks to implement the regulation algorithms

Sample MATLAB code snippet for a simple STATCOM model:

```
```matlab
% Parameters

V_grid = 1.0; % Per unit grid voltage

Q_ref = 0; % Reactive power reference

V_ref = 1.02; % Voltage regulation setpoint

% Initialize variables

V_STATCOM = 1; % Initial STATCOM voltage magnitude

theta = 0; % Initial phase angle
```

```
Kp = 5; % Proportional gain for control

Ki = 1; % Integral gain for control

integral_error = 0;

% Control loop

for t = 1:simulation_time

% Measure system voltage (simulate or measure)

V_measured = measure_voltage(); % Placeholder function

% Voltage error

error = V_ref - V_measured;

integral_error = integral_error + error dt;

% PI Controller for voltage regulation

V_control = Kp error + Ki integral_error;

% Update STATCOM voltage magnitude

V_STATCOM = V_control;

% Calculate reactive power exchanged

Q = V_grid V_STATCOM sin(theta);

% Adjust phase angle to control reactive power

theta = theta + control_algorithm(Q, Q_ref); % Placeholder

% Generate STATCOM voltage source

V_statcom_x = V_STATCOM cos(theta);

V_statcom_y = V_STATCOM sin(theta);
```

```
% Apply to system

apply_statcom(V_statcom_x, V_statcom_y); % Placeholder

'''
```

This simplified code illustrates the core concept: a control loop adjusts the STATCOM output to maintain voltage at a desired level.

## Control Strategies for STATCOM in MATLAB

### Voltage-Oriented Control (VOC)

VOC is a common control method where the STATCOM is controlled in the dq-reference frame aligned with the grid voltage. This method simplifies reactive power control by decoupling active and reactive power components.

Implementation Steps:

[Vd, Vq] = abc_to_dq(Vabc, theta_grid);

[I_d, I_q] = abc_to_dq(Iabc, theta_grid);
```

```
% PI controllers for Vd and Vq

Vd_ref = 0; % For voltage regulation

Vq_ref = -Q_ref / (V_grid); % Reactive power control

% Control signals

Vd_error = Vd_ref - Vd;

Vq_error = Vq_ref - Vq;

Vd_control = Kp Vd_error + Ki integral(Vd_error);

Vq_control = Kp Vq_error + Ki integral(Vq_error);

% Generate PWM signals based on Vd_control and Vq_control

MATLAB Code for Control of STATCOM: An Expert Overview

Introduction

In modern power systems, maintaining voltage stability and power quality is paramount, especially with the increasing integration of renewable energy sources and variable loads. The Static Synchronous Compensator (STATCOM) has emerged as a vital device in reactive power compensation, voltage regulation, and power factor correction. Its ability to dynamically respond to system variations makes it a preferred choice for grid stabilization.

For engineers and researchers, developing an effective control strategy for STATCOM is essential. MATLAB, with its robust simulation capabilities and extensive control system toolboxes, provides an ideal environment for modeling and analyzing STATCOM controllers. This article delves into the MATLAB code implementation of a STATCOM control system, exploring its structure, components, and the underlying control principles.

Understanding the Basics of STATCOM Control

Before diving into the MATLAB code, it's crucial to understand the fundamental control objectives and architecture of a STATCOM:

- Voltage Regulation: Maintain the bus voltage at a desired setpoint.
- Reactive Power Control: Inject or absorb reactive power as needed.
- Fast Dynamic Response: React swiftly to system disturbances.
- Decoupled Control: Separate active and reactive power control to simplify regulation.

Typically, the control system comprises two main loops:

- Inner Current Loop: Controls the inverter's output currents to track reference signals.
- Outer Voltage and Power Loop: Determines the reference current based on the voltage deviation and reactive power requirements.

MATLAB Implementation: An In-Depth View

- System Modeling and Parameter Initialization

The first step involves defining the system parameters, such as line impedance, voltage levels, and inverter specifications. Proper parameter setting ensures realistic simulation behavior.

```
```matlab
```

```
% System Parameters
```

```
V_in = 1.0; % Nominal voltage in per unit
```

```
f = 50; % Frequency in Hz
```

```
omega = 2*pi*f; % Angular frequency
```

```
Ts = 1e-4; % Simulation time step
```

```
Tsim = 0.1; % Total simulation time
```

```
time = 0:Ts:Tsim; % Time vector
```

```
% STATCOM Parameters
```

```
L_line = 0.1; % Line inductance in Henry
```

```
C_filter = 100e-6; % Filter capacitance
```

```
V_dc = 600; % DC link voltage
```

```
```
```

This segment establishes the foundational parameters for the simulation, including the grid voltage, frequency, and device specifications.

- Transformation to dq Frame

Control of AC systems is simplified by transforming three-phase quantities into the dq reference frame using Park's transformation. This decouples active and reactive components, enabling independent regulation.

```
```matlab
```

```
% Clarke and Park Transform Components
```

```
% For simplicity, assume balanced system and sinusoidal steady-state
```

```
% Initialize dq components
```

```
Vd_ref = 0; % Reactive component setpoint
```

```
Vq_ref = 1; % Active component setpoint (for voltage regulation)
```

```
```
```

The code assumes a balanced system for initial simplicity, but in real scenarios, the transformation involves calculating the Park transformation matrices dynamically.

- Designing the Controllers

The core of the STATCOM control lies in designing the controllers?primarily PI controllers?that generate the reference currents based on the voltage error and reactive power demand.

```
```matlab
```

```
% PI Controller Parameters
```

```
Kp_V = 0.8; % Proportional gain for voltage loop
```

```
Ki_V = 50; % Integral gain for voltage loop
```

```
Kp_I = 0.1; % Proportional gain for current loop
```

```
Ki_I = 10; % Integral gain for current loop
```

```
...
```

Tuning these gains is critical for system stability and response speed. The proportional and integral gains are selected based on system dynamics and desired transient performance.

#### - Generating Reference Currents

The outer voltage control loop calculates the reference reactive current, which is then fed into the inner current control loop.

```
```matlab
```

```
% Initialize variables
```

```
V_meas = V_in; % Measured voltage
```

```
V_error = V_in - V_meas; % Voltage deviation
```

```
integral_V = 0;
```

```
% Outer loop: Voltage regulation
```

```
for k = 1:length(time)
```

```
V_error = V_ref - V_meas;
```

```
integral_V = integral_V + V_errorTs;
```

```
% PI control for voltage
```

```
I_q_ref(k) = Kp_VV_error + Ki_Vintegral_V;
```

```
% For simplicity, assume I_d_ref = 0
```

```
I_d_ref(k) = 0;
```

```
end
```

```
```
```

This code snippet demonstrates how the outer loop adjusts reactive current references based on voltage deviations.

#### - Inner Current Control Loop

The inner loop employs PI controllers to track the current references, ensuring rapid response and stability.

```
```matlab
```

```
% Initialize current variables
```

```
I_d = 0; % Direct axis current
```

```
I_q = 0; % Quadrature axis current
```

```
% Loop for simulation
```

```
for k = 2:length(time)
```

```
% Calculate errors
```

```
error_d = I_d_ref(k) - I_d;
```

```
error_q = I_q_ref(k) - I_q;
```

```
% PI controllers for d and q axes
```

```
I_d_int = I_d_int + error_dTs;
```

```
I_q_int = I_q_int + error_qTs;
```

```

Vd = Kp_terror_d + Ki_IId_int;

Vq = Kp_terror_q + Ki_IIq_int;

% Inverter output voltage (simplified model)

V_inverter_d(k) = Vd;

V_inverter_q(k) = Vq;

% Update currents based on inverter voltage and line impedance

dI_d = (V_inverter_d(k) - Vd_line)/L_line;

dI_q = (V_inverter_q(k) - Vq_line)/L_line;

I_d = I_d + dI_dTs;

I_q = I_q + dI_qTs;

end

...

```

This inner loop ensures that the inverter outputs the desired currents, which translate into reactive power injection or absorption.

Advanced Features and Control Strategies

```
```matlab

```

```

```

```
